What command you use to build your program? build the library?

```
$ make all
```

In the Makefile, it will build the executable and the staic library and the shared library. So after we make, we will have: `libmerge_sort.a`, and `libmerge_sort.so`, which are the static and shared libraries respectively.

What command you use to run the executable? environment variables?

```
$ ./merge_sort_static
$ LD_LIBRARY_PATH=. ./merge_sort_shared.elf
```

The first command runs the executable built from the static library. The second command sets the `LD_LIBRARY_PATH` environment variable to the current directory, which allows the dynamic linker to find the shared library when running the executable built from the shared library.
